(54) Title: INTERACTIVE SYSTEM FOR A CLOSED CABLE NETWORK THAT INCLUDES HIGH SPEED ACCESS TO AN ON-LINE SERVICE AND THE INTERNET

(57) Abstract

A system is provided that enhances the interactivity of multimedia information in a closed cable network such as a hotel system or the like when utilized in conjunction with an on-line service. The system includes a multimedia processing system (102), a telephone switching system (108), a video control system (104), a service operations platform (107), and a plurality of interactive devices (110, 125, 112, 114, 117, 119, 121, 123). This system has the advantage of providing compression and/or transmission algorithms to maximize enhancement of the multimedia information. The system allows for enhanced interactivity of multimedia information by a closed cable system while allowing for enhanced access to one or more on-line services with minimum modification to the existing network.

**INTERACTIVE SYSTEM FOR A CLOSED CABLE NETWORK
THAT INCLUDES HIGH SPEED ACCESS TO AN
ON-LINE SERVICE AND THE INTERNET**

5

FIELD OF THE INVENTION

The present invention relates to a closed cable network and more particularly the present invention relates to the transfer of multimedia information within such a network and between such a network and one or more on-line services.

10

BACKGROUND OF THE INVENTION

There are many types of closed cable networks. What is meant by closed cable networks in the context of the present application are networks which are self-contained and the users are easily identified. For example, a multinational or corporate hotel chain provides such a network. In such networks there is typically a facility in each room, office or the like for the presentation of information to a user. Typically this presentation takes the form of multimedia information. Oftentimes, that is information that includes elements of graphics video information that is provided to a customer, employee or the like via a television or like display.

15

20

A critical characteristic of these types of networks is that there should be a path that provides the owner of the network with knowledge of the activities of a particular user on the network. For example, in the case of a hotel, if a customer orders a service, the owner of the hotel can identify that the service has been ordered by that particular customer. The major problem with existing closed cable networks is that they are not fully interactive. That is, it is oftentimes difficult to actively and efficiently access and transport information from and to the network in real time.

25

To efficiently access and transmit information outside the network takes on greater significance when interacting with on-line services and the like. Furthermore, as Internet access becomes more commonplace, it becomes equally important to develop ways for closed cable systems to efficiently and effectively transmit and receive information over such a network.

30

Accordingly what is needed is a system for providing efficient and effective access to multimedia information outside a closed network by a user who is inside such a network.

The system should be one that is minimally intrusive to the network and should not affect its normal operation. The present invention addresses such a need.

SUMMARY OF THE INVENTION

5 A system is provided that enhances the interactivity of multimedia information in a closed cable network such as a hotel system or the like when utilized in conjunction with on-line service. The system includes a multimedia processing plurality of multimedia processing system, a telephone switching system, a video control system, a service operations platform, and a plurality of interactive devices. This system has the advantage of providing compression and/or transmission algorithms to maximize enhancement of the
10 multimedia information. The system allows for enhanced interactivity of multimedia information by a closed cable system while allowing for enhanced access to one or more on-line services with minimum modification to the existing network.

DETAILED DESCRIPTION OF THE INVENTION

The present invention relates to an interactive system for a closed cable network. The following description is presented to enable one of ordinary skill in the art to make and use the invention and is provided in the context of a patent application and its requirements. Various modifications to the preferred embodiment will be readily apparent to those skilled in the art and the generic principles and features described herein may be applied to other embodiments. Thus the present invention is not intended to be limited to the embodiment shown but is to be accorded the widest scope consistent with the principles and features described herein.

Referring now to Figure 1, what is shown in simple block diagram form is a prior art closed cable network. In the following discussion the present invention will be discussed in the context of a hotel system. It should be understood however that there are other types of closed cable networks such as hospitals, educational institutions and many conventional cable head end networks or the like where the principles of the present invention would apply.

The system 10 includes a hotel PBX system 12 for receiving and transmitting telephone calls, property management system 14 and a video control system 16 which could be used to access the pay per view movies or the like. The video control system 16 includes an in-room remote link and is connected to the services operation platform 14. The property management system (PMS) 14 keeps track of the users that order the movies.

The system 10 as above described is not fully interactive. In this type of system there are a number of video units or VCRs located within the system and they are switched in when the appropriate customer or client wants to use the video unit. One problem in this type of system is that these video units cannot be individualized to a particular user because there are simply not enough units. For example, there may be a bank of 64 VCRs which would service a 500 room hotel. Each of the VCRs would have a separate movie. Accordingly, in this case there is a possibility that a particular movie would not be available. In addition, this type of arrangement severely limits the number of choices available.

Another problem with the conventional system is that the users do not easily have access to information outside the system. More particularly, as the Internet and other on-line services become readily utilized it is important to provide the user with easier access to such services. Although these services could be accessed by conventional methods (such as an individual bringing a computer into the hotel room or the like) this is not always possible and oftentimes the particular computer may not be fully equipped to provide such access in an efficient and time critical fashion.

In addition, there is a need to provide high speed access to multimedia information from an on-line service to provide quick retrieval and review of such information. A closed cable system provides the opportunity to develop such an environment. Finally such a system allows for the user to be easily identified for marketing and other purposes. In addition, it would be desirable to provide for a closed system which includes means for interactively accessing a variety of services which are outside the network.

The present invention is directed toward an improvement in a closed cable system which enhances interactivity, particularly for Internet applications. A system and method in accordance with the present invention includes the following elements: a software browser, which can be utilized with a closed cable system, a global distribution architecture, and a way to provide telephone print mapping to such an architecture. The system and method also includes methods for issuance of tickets or coupons in a credit card application. A system and method in accordance with the present invention can be used advantageously in a video game and network environment as well as other types of interactive environments.

A critical feature of the present invention is advertising in such a closed cable system because the user of the network can be easily identified. For example, in most on-line systems and particularly the Internet it is not possible, given the listing of the different

passwords and names utilized by an individual, it is not necessarily possible to identify the user. However, in a closed cable system, such as a hotel or the like, you are able to identify a particular user. Accordingly, for these and the following reasons, this enhanced closed cable system has significant utility over prior art systems.

Global Distribution Architecture

One advantage of the present invention is that Internet access can be speeded by providing a high speed access conduit into the closed cable system. In so doing, an improved system can be provided. In a typical hotel system, for example, the bandwidth of the interconnect to the system is the limiting factor. What has been determined is that by distributing the pieces of information throughout various sites, can provide high speed links to a particular site on the Internet, thereby allowing for quicker access thereto.

Before the present invention is described in detail certain information should be discussed to clarify the utility of the present invention in terms of existing closed cable networks. A multimedia system is a system which provides multimedia information to a user. In a multimedia system, various sensory information is provided to a receiver. In the case of video information, this information can take the form of foreground and background images that display a particular scene. In the case of audio information, the foreground and background signals could be such that the foreground information is speech and the background information is music.

Typically, multimedia systems in whatever form provide this information over a single transmission line. In so doing, the amount and quality of the multimedia information is severely limited by the bandwidth of the transmission line.

The present invention first differentiates between important and less important multimedia information by separating the information into primary and secondary layers through the use of a program model to minimize the bandwidth limitations. In such a system each layer will have its own set of parameters that are important psychographically, however, for example, the secondary layer may not vary as much as the primary layer.

What is meant by a program model refers to psychographic parameters within the multimedia system, that is parameters that relate to an individual's sensory perceptions when encountering multimedia information. These parameters comprise a set of unique and consistent elements for a particular class of multimedia information. In accordance with the

present invention, the multimedia information is separated into different layers in accordance with the program model. Therefore, by way of example, in the instance of video images, the foreground and background information might be divided into different layers. Similarly, in the case of audio information, the news information, weather information, or the like may be one layer whereas the background music may be the other layer.

In the present invention, these layers will be divided into primary and secondary layers in accordance with the information's importance relative to the program model. The most important information is identified and enhanced to provide the best quality information to the receiver of the multimedia information.

In the preferred embodiment, the primary layers will be enhanced in such a way to provide a perceived improvement in quality of the multimedia information presented. In one embodiment the secondary layers are presented that may or may not be enhanced. Thereby the important information or the primary layers that are to be transmitted can be identified and selectively enhanced in accordance with the present invention.

In addition, the primary layers generally can be enhanced through critical psychographic parameters take the form of spatial, color, audio, and temporal variables that occur in the primary or secondary layers.

In a closed cable network such as a hotel system it is important that the multimedia information that is produced, transmitted and received is enhanced in some manner. This is necessary to ensure that high fidelity, high quality information is presented to the viewer. Therefore, it will be possible to bring a superior transmission into the network. It has been possible to provide video information over the telephone lines. However, it has typically been difficult to send high quality video information over the telephone lines due to the bandwidth requirements that are needed to provide such high quality video information.

The present invention is directed towards a method and apparatus for enhancing the interactive multimedia information that is utilized within a closed cable network, particularly information that is provided for a source that is outside of the network. In a preferred embodiment, as will be described in more detail later, a program model can be utilized to separate the information into a usage distribution in the primary and secondary layers. Accordingly, referring to Figure 1A, what is shown is a matrix of usage of the information to bandwidth of the system. The high use information can be stored in a local storage and high bandwidth information can be stored locally. Low use, low bandwidth

information can be stored, for example, in a remote location. To more fully explain such a method and apparatus, refer now to Figures 2-5 which shows a block diagram of a general embodiment and block diagrams of two specific embodiments of the overall system architecture for an enhanced interactive multimedia system for a closed cable network. The overall architecture would be connected to the hotel PBX or the like so as to readily access the transmission lines located therein.

Referring first to Figure 2, the overall general architecture 100 includes a multimedia processing system (MPS) 102 which is coupled to receive information from and transmit information to a video control system 104, an account computer 106, a service operations platform SOP 107, a telephony switching system 108, and an Internet data connection 195. The MPS 100 is also coupled to an interactive multimedia decoder (IMD) 110, a CD/I device 112, a laser disk 117, video camera 121, compact disk (CD) player 125, personal computer (PC) 119, video camera recorder (VCR) 123 and other devices 114. In this system each of these devices can be utilized to provide updatable multimedia information. For example, a compact disk player 125 can be utilized to jump to different places to provide multimedia information. It could be utilized in conjunction with an IMD to augment the fixed media with interactive material (updatable video source) material.

A personal computer 119 can be utilized in conjunction with the IMD 110 as shown in Figure 2A to mesh a composite signal (audio, video) utilizing a multimedia selection. Some examples for the use of such a system are on-line services, games or maps and the like.

The personal computer 119 could be utilized as a device in a room, or it could be in the basement of, for example, the hotel system to provide for access to different data. Referring now to Figure 2B, which is a partial block diagram of a closed cable system, what is shown is a data connection 195 coupled to the MPS. This data connection, for example, could be coupled to the Internet, via satellite, telephone or cable feed. This data connection 195 allows for access to the Internet and also allows for passing that connection to the PC 119 to provide a video output via converter 197. That video signal is then converted to be provided to the television. Once the video signal is provided, for example, there are several ways to control access to the Internet via that converted video signal. For example, a keyboard could be used which is directly wired to the cable. Also a keyboard could be used to provide an infrared connection to the TV or could provide a connection to the telephone.

In addition, a remote control could be utilized which includes some type of mapping which would allow for the selection of materials such as an on screen typewriter template. In addition, another example would be a telephone keypad which would provide a DTMF tone that would combine with a translator to provide data string conversion. This in turn would drive the input to the Internet selection.

Finally, a laptop PC could be used that is connected to the telephone or cable. Software within the laptop PC could direct modem connections to the MPS to link the system to the MPS.

A return path must be provided through the network. One way to provide a return path is through the video cable system, either via an infrared connection or a direct data connection. Another means for a network which could be utilized to provide the return path is the telephone system via the PBX.

The different in-room devices can interact with either of the networks in a variety of fashions. For example, the keyboard and mouse could be used to provide a direct cable box to the video cable system or could be by wire directly coupled to the video cable system to access and control access to the Internet from the room.

The keyboard/mouse that is wired could also be directly coupled to the telephone system. An infrared keyboard/mouse could be attached through a cable box to access the video cable system or could be coupled to the telephone system or PBX.

In an example, the keyboard/mouse could have an infrared emitter which provides signals directly to the cable box for controlling the cable system directly. In another embodiment the remote control utilized for the television in the hotel room could be utilized within a hotel room, for example, to access the cable system as well as making selections on the cable system through the keypad and a mapping arrangement, e.g., on screen keyboard or hot area, cursor selection.

The telephone keypad can also directly access the MPS through a key data string conversion to drive the input for the Internet selection. The telephone keypad could be utilized as a device that could mimic the point and click motions necessary to access the Internet.

Referring now to Figure 2C, an overlay of the telephone keypad could allow certain keypads to mimic the point and click characteristics of the typical Internet access. By using the overlay to indicate that certain keys are for up, down, left and right notions, the

telephone keypad could be utilized advantageously to access the Internet.

This type of system can be utilized advantageously to provide high speed access in a closed cable system, such as a hotel or the like, service center for the Internet.

Referring now to Figure 2D which is a closed cable system for use with Internet access, what is provided is a dish 196 that receives a satellite feed which can provide information to a server 199 via a PMS 207. The server 199 is connected to a direct outside telephone line for transmitting calls and can receive in-bound phone calls via a PBX system 211. It is also coupled to a video network 213 in the hotel environment which in turn is coupled to individual work stations 215. Finally, the network includes a printer coupled to the server 199. This system could be utilized to provide high speed Internet access.

To provide a more detailed view of a high speed hotel Internet access system service center 285, refer now to Figure 2E. In this Figure, what is shown is a plurality of Internet access workstations 215 which are coupled to a network 295 and a satellite communications controller 297 which is coupled to a high speed Internet access satellite dish 294. In addition, there is a server which is coupled to a printer. This service center will allow for high speed access through the satellite feed.

Figure 2F is a diagram of a national satellite network. In this environment workstations are the point of entry into the Internet access system. Outbound communications will take place over conventional telephone lines while inbound communications will be provided from remote web sites to be delivered to the workstations via the Internet control system. Through this asymmetrical provision of information communications, data can be provided in a more efficient manner.

Referring now to Figure 2G, what is shown is what would be displayed on a workstation in the service center. The user could access various areas either within the closed cable system or on the Internet using traditional keyboard mouse interactions. Hence, as is seen by clicking on "7" NETGATE could be entered to provide Internet access. Hotel guests could, for example, use workstations as a point of entry into the high speed Internet access system. Outbound communications will take place over conventional telephone lines while inbound communication from remote web sites will be delivered to the work station via the satellite system. Through this system, an improved speed of access is provided.

Generally, a remote control network for access to the Internet is provided. Through this system, an Internet session can be displayed via keypad, telephone set, or remote

control. A PC application, for example, which would allow for access to a network is through the PC application of video games. Through this access the PC can be used to control access to the network. This system would allow for multiplayer games to be utilized, for example, over the Internet which will allow for multiple players to play, not only within the hotel system but also out to the Internet community.

One of the advantages of using this system in the Internet is that there is the ability to tag different demographics directly through the closed cable system. One of the weaknesses of the Internet is it is not easy to track the particular individuals using the Internet on a consistent basis. For example, typically on the Internet a user may have several different user names for performing certain searches or other requests. The system in accordance with the present invention provides advantages thereover such as, one could present to website certain information about a particular user. The website could then allow for a unique presentation to a user. For example, if a particular user is reviewing an automobile website, (i.e., Mercedes Benz), then links to that website can be customized for the particular user, such as to a top of the line car stereo system or the like. Through the use of this information, a tag can be provided to identify a user. This tag can be used in a variety of ways to provide demographic information to a particular advertiser. Hence that data could be encoded, packetized and then provided to the advertiser in a particular format so that the advertiser would know the buying patterns and other information about the particular user. This significantly enhances the value of the communications.

Referring now to Figure 2H, what is shown is a hotel intranet system. The system includes a Network Center 151 which receives and transmits information to a plurality of hotels 153a-153c. There is a common database 159 which includes a variety of value information. The value information might include billing information, profile information of the user. The system can also be linked to use databases, demographic client marketing databases. This system provides a clear mechanism for locating or establishing contact with a user.

In an example, the user can check in to a hotel within the user system and be immediately identified by the hotel. A delivery cycle of a message to such a user might include turn-on in room message light on the telephone or the like. That in room message could be a voice mail message, email message, facsimile or some other type of message.

Accordingly, in one embodiment, the message would be to a user, "Hello 'user' (any

name) you have five email messages, two outside voice mail messages, six facsimiles and five downloads of software." The user could attempt to access this information through a business center as before described, from an in-room TV (i.e., Internet, intranet or otherwise), through the telephone or through a printer or the like located either in the user room or at the hotel front desk. Through this hotel messaging interface there is provided the ability to provide synchronization between the PBX telephone and the Internet. By providing a connection to the website of, for example, an internet registration website such as AT&T, there is the ability to link through that website a PBX connection directly through a telemarketing or customer service group to serve the needs of a customer AT&T or another long distance carrier. Since the hotel database includes a profile such as likes, bookmarks, setting of the television that allows the hotel to set up a custom interactive environment.

A VCR 123 or CD player 125 could be utilized in such a system, for example, for movie preview, catalog shopping, and a music listening system from the Internet. Through this system full interactivity could be obtained.

Video conferencing can be implemented for point to point or point to multiple point video conferencing. For example, referring now to Figure 2I, what is shown is a point to multiple point video conference system 500. In this type of system, a video conference room (VC) can be utilized to transmit to multiple sites. This system can be utilized with the IMD 110 to provide updatable multimedia information.

Similarly, a point to point system, in which there is a video camera in each guest's room, can be utilized. In this embodiment, a video multiplexer can be utilized to send updatable multimedia information from point to point (room to room) dependent on the type of information presented.

An advantage of this system is to provide means for switching between alternate multimedia information at the head end. This allows for switching between analog and digital; data and graphics, music and video, etc. To more fully explain the advantage of this feature refer now to Figure 2J. Figure 2J shows a multimedia multiplexer (MM) 135 coupled to an IMD 110. In this embodiment the MM 135 can send information from a plurality multimedia sources to the IMD 110.

In a preferred embodiment to provide for maximum resource allocation refer now to Figure 2K which shows a global multimedia multiplexer (GMM) 137. The GMM 137

would typically include a plurality of multimedia lines ($mm_0 - mm_n$) for receiving multimedia source material. The GMM 137 receives information from a plurality of multimedia devices such as a PC, VCR, LD, CD-ROM, and CD/I devices. It can also be utilized as a network output of a PC or network access to the Internet. The output of the GMM 137 is provided to a plurality of IMDs 110 ($IMD_0 - IMD_n$). The GMM 137 receives signals from a control channel 139 either from a MPS or the IMDs or other outside source. Through this device any multimedia source or combination of sources ($mm_0 - mm_n$) can be directed to any decoder or interactive channel ($IMD_0 - IMD_n$). This GMM 137 can be implemented in a variety of ways, for example, it can be a digital crosspoint switch.

Through such a device a combination of multimedia devices can be utilized to produce a composite signal. This type of system can also be described to separate the information into primary and secondary layers as applied to a network. Accordingly, some of the information can be stored in the IMDS locally, for example, and some information can be stored remotely, dependent upon the bandwidth usage configuration of Figure A.

Referring now to Figure 1B, the GMM can be utilized to control the network pieces such as the video conference (VC), a personal computer (PC) and/or an IMD such that an integrated composite website can be created which can provide efficient access to critical information.

Referring back to Figure 2, the cable feed line in turn is coupled to the video control system 104. The account computer 106 and the SOP 107 are also directly coupled to the telephone switching system 108 via line 120. The telephone switching system 108 is capable of sending and receiving outside calls. The video control system 104 is capable of sending and receiving a remote signal from a cable system, telecommunication system or the like.

Another portion of the invention is an interactive voice response system 111. This system includes a telephone 113 which connects to the telephony switching 108 via telephone links. The telephone 113 also could include a credit card slot. There is also included within the system 111, a remote control 900 which will be described in detail later and a television 115 which is coupled to the cable 116.

In this general embodiment, the multimedia processing system (MPS) 102 receives program source material from the SOP 107 and from the control system 104. The control system 104 can be a pay per view system such as a On-Command™ Video or a different

type of service, such as a shopping, buying movie or airline tickets, or the like. The MPS can also operate an interactive voice response program independently or integrated into other interactive multimedia programs.

5 The SOP 107 is utilized for receiving e-mail, facsimile and voice messages. The SOP 107 can also be utilized in conjunction with pagers and the like to relay messages. By linking the account computer 106 to MPS 102 messages can be displayed on a monitor within the guest room. In addition, faxes can be displayed on the television and could be forwarded to other locations.

10 A master multimedia processing center (MPC) 109 is also coupled to the closed cable system 100 via connection to the MPS 102. The MPC 109 is coupled to a plurality of closed cable systems to provide enhanced interactivity thereto. Referring now to Figure 2L what is shown is a block diagram of the MPC 109. The MPC 109 comprises an interactive multimedia mastering system 111 which receives program source material from various outside sources and a MPS 102 which receives source material from the IMM 111 and can also receive data information over a program port 113 and an auxiliary port 115.

15 Referring back to Figure 2, a critical portion of the system 100 is the telephone switching system 108 interface to an outside source of information. Through the use of this architecture the switching system 108 can be controlled to provide the appropriate information to the user. Through the use of the interface devices (IMD 110, CD/I 112 and the other device 114) and the MPS 102, the switching system 108 can be controlled in such a manner that the user doesn't have to remember a telephone number to obtain the desired information. This control can be accomplished through either a digital link that is directly interfaced to the telephone switching system 108 or through an analog link where only a normal phone connection to the system. Through either of the systems an emulation of the customer actions would be undertaken.

20 In a typical example, a call is made by the user to order a service. The MPS 102 places call to the room through control of the system 108. The room telephone will ring and the MPS 102 will send a message to the switching system 108 that the customer would like to access a service, in this case, a restaurant where the customer would like to make reservations. It should be understood in the alternative to the above that the restaurant could be called first via the system 108 and then the MPS 102 would call the customer back. The switching system 108 will then call the restaurant, introduce the caller and then the

restaurant will be linked to the room. All of these activities are done transparently to the user. Through the use of this system 100 it is also possible to print out faxes and or receipts directly at the front desk of a hotel or the like.

5 The system 100 is capable of transaction processing via the multimedia in a variety of ways. For example, transactions can be processed by posting billing information to a computer within the closed cable system, a facsimile ordering system within the system or through a voice order processing.

10 The MPS 102 will provide and receive information relating to movies and other services from and to interface devices 110, 112, and 114. The interface devices 110, 112, and 114 are in the hotel facilities connected either to the hotel video cable system through use of the video/audio outputs or connected via digital links from interface devices 110, 112 and 114 in each guest's room.

15 Referring now to Figure 3 what is shown is the preferred embodiment of a MPS 102. The MPS 102 comprises a distributed computing architecture. The distributed computing architecture includes a master node 200 that has, in this case, three server nodes 204, 206, and 208 for the IMD, CD/I and the other devices respectively. The other devices that could be coupled to MPS 102 are, for example, but not limited to video games, a CD ROM device, a personal computer, or a specialty device such as a translator or gaming device such as a video slot machine or the like.

20 Each of the server nodes 204, 206 and 208 have client nodes 210, 212, 214, 216, 218, and 220 connected to the respective interactive devices. Attached to each of the clients nodes 210, 212, 214, 216, and 218 ports 220. When connected via the existing networks or the MPC 109 (Figure 2a) and then on to connection to the interactive devices 110, 112, and 114 (Figure 2) which has its own processing storage and computing structure the entire network can be operated as a massive distributed computing environment.

25 This environment shares all dimensions of computing, storage, transmission and peripheral resources (printing, product ordering, mailing functions, etc.). This type of computing architecture would include dynamic port allocation and would include incremental failure characteristics to allow for robustness of the MPS 102.

30 In addition through the use of this interactive system 100 of the present invention a multiplicity of different interactive devices can be utilized and no modification to the device need be made to allow for devices' use within the system. Accordingly the link between the

MPS 102 and the interactive devices can be a serial link, a CD/I link, a cable link such as ethernet or telephone connection via a simple infrared relay control link. Since the MPS 102 can transmit and receive data as well as control information it can operate utilizing a wide range and types of interactive devices such as video games, CD ROM, personal computer or specialty instruments such as translators via an Internet or other on-line services means.

In a first more specific embodiment shown in Figure 4, the multimedia processing system (MPS) 102 receives program source material from the services operation platform (SOP) 107' and from a pay video control system 104'. The control system 104' can be a pay per view system such as a On-Command™ Video or a different type of service, such as a shopping, buying movie or airline tickets, or the like.

The SOP 107' is utilized for receiving e-mail, facsimile and voice messages. The SOP 107' can also be utilized in conjunction with pagers and the like to relay messages. By linking the SOP 107' to MPS 102 messages can be displayed on a monitor within the guest room. In addition, faxes can be displayed on the television and could be forwarded to other locations.

The multimedia processing system 102 will provide and receive information relating to movies and other services from to interactive devices 110' and 112'. The interactive devices 110' and 112' will be located in the hotel facilities connected either to the hotel video cable system through use of the video/audio outputs or connected via digital links from interactive devices 110' and 112' in each guest's room.

In a second more specific embodiment shown in Figure 5 the architecture is similar except that there is an IMD 110 in each guest room. The IMD 110 can also be used within an interactive voice response system 119 to provide a more complete interactive system. In this embodiment, the IMDs 110" can be utilized to provide the interactivity for each room. The structure of the IMDs 110" will be described in detail later in this specification.

The IMDs 110 can take on many different forms dependent upon how much intelligence is located in an IMD 110 relative to the system architecture 100. The system architecture 100 shown in different aspects in Figures 2-5 provides program material which will enhance the interactivity of information that is transmitted along the video network. Accordingly, what the system architecture 100 represents, in fact, is an additional network which would receive information from the program source which would also be part of the existing closed cable system could receive information outside of the cable network through

the Internet or other on-line services system. The system architecture 100 will then be utilized to provide for enhanced multimedia information through psychographic manipulations or other enhancements to the systems to provide for an improved interactive closed cable system.

5 Within each of the IMDs 110 of the system 100 is an optimization technique for enhancing the quality of the multimedia information that is present. To more specifically describe this optimization technique, refer now to Figure 6 which is a block diagram of an optimization method in accordance with the present invention. This optimization technique has been described in detail in U.S. Patent Application Number _____, entitled, "Method for
10 the Production and Transmission of Enhanced Multimedia Information", having a filing date of

_____, assigned to the assignee in the present invention, and that patent application is incorporated by reference in this application. The following paragraphs along with the accompanying figures will provide the details regarding the optimization method and how it
15 will be used advantageously to provide an enhanced interactive multimedia system.

The purpose of the IMD 110 is to provide maximum interactivity while at the same time providing maximum retention of the program model. It is also important that there be minimum transit time for the interactivity while the information has maximum replication. Therefore, it is very important that the program model psychographic parameters be well
20 described. For example, the spatial, color, temporal, audio response, material concept, contention perception all should be very well described and defined in the program model.

Referring again now to Figure 6 what is shown is a first embodiment of a flow chart for providing an enhanced interactive multimedia information that utilizes the principles of the present invention. The flow chart 300 comprises the steps of providing a program model
25 to a separator. The separator 302 will divide the information into primary and secondary layers of interactive multimedia information. The separation is automatic and can be accomplished in a variety of ways. For example, the layers can be separated by production sources. In another example, separation can be accomplished through key coding the layers. As previously mentioned, the information with regard to Figure 1, the information can be
30 separated in accordance with a matrix of bandwidth and used to provide storage either remotely or locally dependent upon the particular configuration. In yet a fourth example, the layers can be spatially separated or separated by the various colors. The layers would be

separated in accordance with use and bandwidth requirements to provide enhanced interactivity. Finally, layers of information could be separated by a filtering process.

The primary layers are provided to the compression generation block 304. There are a variety of ways that the multimedia data can be changed or generated to use less bandwidth. For example, compression algorithms or their equivalents could be utilized to reduce the bandwidth used. In addition generators, such as in a tone generator system, could be utilized to reduce the bandwidth required. Finally, key coding systems could be utilized to reduce bandwidth use. Such systems will be discussed in more detail later in the specification.

In this embodiment, the primary layer is provided to an encoder where the primary layer is prepared for transmission (block 308). Thereafter the primary layer of information is decompressed (block 110). The primary layer is then decoded and mixed with the secondary layer of data information (block 312) to provide an enhanced interactive multimedia image (motion, video or other) or data to a display.

Similarly, the secondary layer is compressed through block 314, encoded (block 316) and then transmitted to block 318 to decompress and mix block 310. The two signals (primary and secondary) are then sent to display 312.

In this embodiment, for example, for the optimization of video images, the primary layer can be the foreground image, the secondary layer can be a background image. Through the use of this type of optimization technique multimedia information can be enhanced while at the same time utilizing significantly less bandwidth. In addition, by optimizing both layers, full motion video is possible.

To more fully understand this feature refer now to the following discussion. In a typical interactive multimedia system the information is all sent along one layer. The information that can then be transmitted is limited by the bandwidth of that layer.

In the prior art, the interactive multimedia information that could be transmitted along typical networks or transmission paths that are very limited because, for example, in the case of video images the bandwidth is not adequate to provide a high quality image to a display.

Hence, in the present invention, by separating the multimedia information into primary and secondary layers and thereafter compressing the more important information utilizing well known compression algorithms, a system is described that can produce

enhanced interactive multimedia information that easily be transmitted over existing networks.

To more fully describe the psychographic enhancement feature of the present invention refer now to Figure 7 which shown the various possibilities from a particular program model. What is meant by program model could be a specified modeling language, for example, HTML or VRML. The form of the various components of the modeling can be specified for the particular user. The program model is provided to the separator 302 of the multimedia system.

Psychographic enhancements are critical to the improvement in interactive multimedia transmission and reception enhancements in the context of the present application is information that is not transmitted but operates on, operates in conjunction with, or operates as a supplement to transmitted multimedia information. There are three separate categories that will be described that relate to psychographic enhancements.

The first category will be described as a cross correlation between the information that is being transmitted and being enhanced due to the presence of information that is not transmitted. Dithering of image is an example of this in that dithering masks artifacts of images that are present and that improves the image quality. This type of system does not remove the artifacts but actually just masks imperfections. A second example in the audio arena where secondary audio materials such as a sound of an ocean or the like which might mask problems in the audio quality of the primary sound (voice, music or the like).

The second category is where the signal is actually changed without the use of any control signal; for example, through interpolation or some other technique. The typical example of that is a graphic equalizer in which certain frequencies are enhanced depending on the range of the particular device. Another example of the second category is to frequency or amplitude compress a certain signal so as to further enhance the frequencies that are being transmitted. It is also known to use various filters to sharpen or provide certain information that will actually modify the signal without controlling it per se.

Finally, the third category is using the primary and secondary information to drive the other generators that might be present within the multimedia system. This can be utilized to either enhance the multimedia information or enhance the program model. An example of this is the use of real-time graphics frequency spectrum displays to enhance a music juke box type of program model.

As is seen in Figure 7, the primary multimedia information layer can be compressed to reduce the bandwidth utilizing well known algorithms. It is also seen that the signal can be replaced by a generator that is responsive to the primary/secondary layers signals. Finally, a key code could be used to cause information to be provided from a look-up table or the like.

Although all of the above methods provide advantages in accordance with the present invention, key coding has some additional non-obvious advantages when utilized in the optimization system of the present invention. In the following paragraphs the use of various key coding systems will be described generally along with their attendant advantages.

Typically, when looking at an interactive multimedia information signal there are several components of that information. The first component is the data or the multimedia information itself that is being conveyed. The second component is referred to as program model dynamics. That is the changes that occur in the interactive multimedia information due to, for example, a fade that allows for a transition from one scene in the graphics or video image to another. Conversely, if you want to wipe away an image there is information associated with the multimedia data that would call out for that transition to change efficiently.

Finally, the third category of interactive multimedia information is what will be referred to in this specification which will allow a particular device or system to go from one category to another. In a typical interactive multimedia information system all this information is required to adequately transmit such information.

In its simplest form, a key has an identifiable code which dictates the commands on the other side of the device. The clearest example of such a keying system would be the very simple dual tone multi-frequency (DTMF) signal. This type of signal can be used in the telecommunications area to provide keying for low bandwidth protocol. These keys would then command a code table on the side of the network to provide certain information about the multimedia information to be displayed without requiring actual transmission of the multimedia information.

A more specific version of this type of key coding is what will be referred to in this specification as control information keying. What is meant by controlled information keying is where a key code is utilized to access particular types of commands which can

then be used to control other items on the other side of the network.

Such a table would then be utilized to access a certain set of multimedia information in the network. A final version of key coding will be called program branching keying is described by each of the keys representing a certain branch identification. Thus in this type of key coding the key is cross referenced to a particular branch of the interactive multimedia program where each of the branches allows plurality of functions or commands to be accessed in order to replicate the program model.

The important feature that is provided by all of these types of keying coding arrangements is that information already present on the network can be utilized. Therefore, the processing power inherent in the network or the system being accessed can be utilized rather than having to have to provide that processing power within the optimization system itself.

It is also important to develop means to improve the transmission quality of the multimedia information, for example, the information may be transmitted utilizing a typical transmission algorithm with standard communication file data transfer protocols. The interactive multimedia information could also utilize specialized protocols that are optimized for the particular interactive multimedia information that is to be transmitted. In so doing the algorithm for the compression algorithm can be interactively matrixed with the transmission algorithm to provide the highest quality information with the maximum interactivity with the minimum transmission line.

Referring now to Figure 8, what is shown is a flow chart that shows the cooperation of the transmission algorithm with the compression algorithm to produce a high quality multimedia image. The flow chart comprises providing a program model in which the primary and secondary layers are separated (block 402). The primary layer is compressed and encoded (blocks 404 and 406).

A control element (block 410) is utilized to control a compression matrix and a transmission matrix. These two matrices comprise a plurality of compression algorithm and transmission algorithm respectively that are interactively controlled such that as the various algorithms are detected the quality of the multimedia information and the speed of the transmission are interactively determined.

The quality of the information could be determined manually or through the use of some control circuitry. It should be understood that these same matrices could also be used

on the secondary layer. It was not shown or described for purposes of clarity and simplicity.

Referring now to Figure 9 what is shown is a block representation of a matrix of compression algorithm with transmission algorithm that could be utilized in accordance with the present invention. The circles 502 aligned in the vertical direction are the compression algorithms. The rectangles 504 aligned in the horizontal direction are the transmission algorithms.

For example the compression algorithms could be JPEG, a generator with MIDI, and a key for a weather map background. Similarly, the transmission algorithms could be optimized for JPEG, data compression for MIDI, or DTMF for key transmission type algorithms. To provide the highest quality multimedia information while at the same time utilizing minimum bandwidth the different algorithms can be selected in an interactive manner.

Hence, a first compression algorithm could be selected along with the first transmission algorithm. The multimedia information is reviewed either for image or audio quality than a second compression algorithm is selected. The multimedia information is reviewed and if the quality is not acceptable then a second transmission algorithm is selected. The quality of the information is reviewed. This process is repeated until the highest or desired quality multimedia information and interactivity speed are provided.

The multimedia information derived from the compression/transmission algorithms can be analog or digital in nature. However, in a digital signal there are certain other features that can be taken to advantage that can be utilized in accordance with the present invention.

It is known that digital data information is typically sent in a file which specifies certain parameters of that data and the data information itself and within the data information itself is information which may not change for a certain set of files. In the case of an image file, the header information may specify the dimensions, pixel depth, and certain other features of the particular image. This file may take up a much as twenty percent of the data file.

Conversely, in a file such as MIDI music file which comprise a plurality or a series of music notes, the header may include instrument information, related information and characteristics of that particular file. In both of the above mentioned examples, the header information may not change. through the use of the optimization method the amount of

information may be significantly reduced over time.

Hence, in the case of the image file, the header could be sent first with no compression or with lossless data compression as the secondary file because it will always remain the same. The data file itself can then be compressed down to its smaller size.

5 Another method for enhancing the psychographic parameters is to provide some form of error detection and adjustment. As has been mentioned before the detection and adjustment can be accomplished via interpolation of the error. An alternative method of error corrector is through an error correction/transmission algorithm. What is meant by this, is relating the transmission to the compression to enhance interactivity.

10 In this type of system before the file is sent the base file is compressed and then decompressed. This decompressed file is called an expanded compressed base file. The expanded compressed base file is then compared to the original base file and an error file is then developed (the error file being the difference between the base file and the expanded compressed base file). The error file is compressed and sent along with the compressed version of the base file down the line. These files are then combined and decompressed to provide an enhanced image.

15 Referring now to Figure 10 it is seen that a data file utilizing this technique could initially be separated into primary and secondary layers. The primary layer could be compressed using a first compression algorithm, the header could be sent first along a first transmission path and the compression signal could be sent along a second transmission path.

20 Therefore, the amount of storage necessary for the file is significantly reduced through secondary compression techniques. This information can then be transmitted or stored across the network rather than having to have all the information stored within a particular device within the optimization system.

25 It should be understood by one of ordinary skill in the art will recognize that the number of algorithms is not limited to the number shown in the figures. In addition it should be recognized that the order or the selection of the algorithms could be changed and that would be within the spirit and scope of the present invention.

30 The present invention has been discussed in terms of compressing the primary layer or layer and by compressing and transmitting that primary layer in a particular way the interactivity of the system is enhanced. It should be understood that it may be equally

important to enhance secondary layers to produce the same effect.

Therefore, it may be important to enhance the secondary layer, it may be important to enhance the primary layer or it may be important to enhance both. Therefore, the present invention through the use of compression and transmission algorithms and through the psychographic enhancement of the program model can enhance interactivity of a multimedia system.

It should also be understood that the function of the compression and transmission algorithms can also be done through other means; for example, a signal generator could be used to provide the same information. That is, a signal generator responsive to a particular layer or layer of information could be utilized to provide that information or some level of information that is representative of that layer. For example, a tone generator responsive to a signal from the secondary layer to provide the tone that would be representative of that secondary layer.

Conversely, some type of graphics generator could be utilized to respond to that same type of signal to provide a certain type of graphic image in a video system. Finally, it should also be understood that the psychographic parameters can be adjusted by human operator or in the alternative can be adjusted or modified by an automatic means.

As has been before mentioned, it also is very important in this system architecture to have an interactive multimedia device 110 which will allow for the receipt of high quality multimedia information from the system architecture. The IMDs 110 can be either located in the facility in the basement or are utilized with each of the television monitors within the hotel or hospital room to provide enhanced audio, video and graphic information within the closed cable system.

Figure 11 is a preferred embodiment of an interactive multimedia decoder (IMD) 110. The IMD 110 comprises several components. The cable or telephone line is coupled to a multimedia modem 1102. The multimedia modem 1102 is coupled to a multimedia memory 1104 which can be an expandable dynamic random access memory (DRAM) 1104. The multimedia modem chip 1102 provides data to a multimedia decompressor device 1106. The multimedia memory 1104 provides data to graphics/character generator 1108, speech generator 1110 and music synthesizer 1112. In addition, the output of the generators 1108, 1110, and 1112 are provided to a video control chip 1114. Video control chip 1114 provides signals to a standard television display and receives signals from a standard

television source. The multimedia modem 1102, the multimedia memory 1104, the multimedia decompressor 1106, the multimedia digital/audio control 1108, the video control chip 1114 and music synthesizer 1112 are all ultimately controlled by an interactive control interface 1116 which manages the operation of all of the above elements. The video control chip 1114 is coupled to a standard telephone keypad input or for a television remote-type device or a special IMD remote can be utilized in a variety of ways which will be discussed in detail hereinafter.

Personalized and Demographic information can be stored on the IMD 110, the MPS, or the PMS including age, sex of the user along with technical information (IMD serial no, generators available). Therefore, upon connecting to the MPS 102, the IMD 110, or PMS can both forward this stored information either at the beginning of the session or anytime afterwards. This information can then be updated through the MPS 102 or directly at the IMD 110 through selection using the keypad or outside dialing or remote or by receiving the data from the MPS 102.

Accordingly this information provides the basis for highly accurate market research and commercial monitoring. Through the IMDs and MPS real time information can be provided to the supplier of the information. This information can also be utilized to provide interactive advertising based on the choice of the advertiser as well as the demographics of the viewer. The type of information that could be useful for example would be the logging of each key stroke made on a remote control thereby monitoring the "browsing" or viewing habits of the customer in response to either interactive material supplied by the IMD or synchronized material from the cable head-end 122.

In the case of room shopping, a guest can select information for presentation and then can choose items and then bill items to the room via the Internet or other means using the previously mentioned high speed access Internet system. As an alternative, the MPS 102 can allow for the use of a credit card to forward information on to an automated order system or to an operator. In addition, this type of system could allow for a facsimile receipt to be sent back to guest via the television monitor within the room.

Another mode of operation is the delivery of multimedia information during the period that the communication network is not in use. In this way large amounts of multimedia information can be efficiently transmitted and stored in the IMD for later review and enhanced interactivity.

The function of each of the different components in a preferred embodiment is described in a summary fashion below.

Multimedia Modem 1102

- 5 A. Responsible for all communications between cable or phone line, optional serial port, interface to multimedia memory, multimedia decode, audio control, and processor control modules.
- B. Supports standards protocol for half-duplex, full duplex, and half-duplex high speed operation.
- 10 C. On-chip encode/decode capability, D/A, A/D for voice, facsimile, and data functions.
- D. Dual tone multi-frequency (DTMF) detect and generation.
- E. Auto-detect voice/facsimile/data switch for transparent mode transition.
- F. Incorporates controller unit with binary file transfer, facsimile, data, and voice
- 15 modes, and optional proprietary multimedia processor control optimized protocol firmware.
- G. Firmware allows IMD to use multimedia modem to perform call processing function including telephone call dialing and connection, unattended receipt of data and fax among other functions.
- H. Include ability to decode data from video cable signal including VBI encoded data
- 20 or data encoded in the video signal itself outside the VBI.

Multimedia Memory 1104

- A. Nominal DRAM or VRAM for image mixing/processing, and auxiliary multimedia data store.
- 25 B. Nominal ROM for resident IMD control program.
- C. Optional co-resident DRAM for multimedia data store and program/data store.
- D. Optional non-volatile storage (extendible).
- E. Memory control unit for VRAM/ROM/DRAM and non-volatile storage.

30 Multimedia Decode 1106

- A. Responsible for real-time decompression of images transferred to or stored in the IMD 110.

- B. On chip inverse discrete cosine transform processor.
- C. Reverse quantizer decoder/tables.
- D. Built-in zoom, pan, chroma key, mix from compressed data incorporates interfaces to video data bus, multimedia memory, multimedia modem, video control, and microprocessor control sections.

Video Control 1114

- A. Responsible for all IMD 110 video mixing, enhancements, and display functions.
- B. Pixel processor for mix, zoom, pan, chroma key, transform on pixel data, transitions.
- C. Graphics processor for figures (e.g., rectangles with color fill) generation, sprites, text with foreign characters, and scrolling.
- D. Digital to analog conversion, analog to NTSC, NTSC video plus stereo audio to RF.

Graphics/Character, Speech Generator, Music Synthesizer 1108, 1110, and 1112

- A. Responsible for enhancing received analog/digital audio, music synthesis generation, and overall analog mixing and audio effects.
- B. Incorporates decoding burden.
- C. Sampled instrument synthesis from compressed MIDI input.
- D. Built-in micro-controller for multi-task generation.
- E. Dual analog source mix, digital audio and synthesizer mix, analog audio control (volume, bass, treble, balance) for output to analog left/right audio.

Interactive Multi-Task Processor 1116

- A. Responsible for multi-task execution of resident and downloaded IMD code for operation in conjunction or independently of the MCPS.
- B. Master/slave microcontroller architecture for multi-task control of communications, multimedia memory, multimedia decode, digital video control, digital audio/synthesis, and interface management.

In a preferred embodiment, the IMD 110 will be utilized with a television monitor to transmit and receive multimedia information. Hence, the IMD 110 can be utilized in the case of movie for access and to transmit an almost unlimited number of movies to a particular user. Therefore through the use of the IMDs in the system a more fully interactive

system is possible. In addition, through this system a variety of other services can be provided for the user such as advertisements, shopping, airline ticketing, entertainment and the like.

5 Another critical feature of the IMD 110 is to have a remote control that will work in conjunction with the television or other display to provide enhanced multimedia information from the Internet or other on-line services. To more fully explain this feature refer now to Figure 12. The remote control 900 looks much like a telephone keypad. It has the numerals (0-9) and symbols (*-#) that are part of an ordinary telephone keypad. It includes an enter key 902 that is typically utilized to change information or change channels in the case of a
10 television set. The control 900 would also include a volume key 904 and a channel or memory select key 906, a connect key 908, a telephone call key 909 and a multimedia toggle button 910. The telephone call key 909 is utilized to place a call to a designated telephone number or to a number associated with the multimedia information being viewed. The remote control 900 also includes a keys 911, 913, 915 that will control the fast forward,
15 reverse, and slow motion of the display device.

The remote control 900 could also include a credit card slot 912. This credit card slot 912 would be utilized by the viewer to allow for the purchase of certain items directly while viewing the television screen. The credit card slot 912 could also be utilized as an indicator that a certain room is being occupied by a particular person. This indication would
20 preclude the need for a separate inputting of the relevant user information for billing information. The credit card information could also be accessed by a credit card slide that is physically connected to the television by passing the information through the remote control cable back channel.

Finally, the control 900 includes special effect keys 916, for example, for allowing
25 for the browsing of a multimedia directory while simultaneously displaying a picture in the picture of the current broadcast TV channel. The remote control 900 can operate in an emulated keystroke mode in which pressing one key may be utilized to emulate a combination of keystrokes. In addition a call button may be provided which would allow for sending valid numbers to another location. The remote control 900 also has the
30 capability of emulating other remote controls. For example, through the MPS different types of signals can be mapped with the remote control. The MPS provides the translation of the signals of a CD/I device for example.

The remote control 900 could utilize a radio frequency signal or audio signal to interact with the receiver and/or IMD 110 for the control of the IMD 110, control the selection of multimedia information, and for the control of other devices. It is also known that a more conventional remote control could be utilized such as one that controls a VCR or a television and its use would be within the spirit and scope of the present invention. The remote control 900 also includes a positioning function. Accordingly, a motion detector or the like can be utilized within the remote to allow for pointing the remote at the television monitor to transmit certain information.

Another feature of the above-identified system architecture is that the program information can be linked to the network to provide for enhanced interactivity and program quality. This has particular advantages when utilized with on-line services. For example, the program source can follow or be synchronized with the cable or broadcast feed to provide for enhanced distribution of program information. One specific example of this to take a new program, like CNN broadcasting, which consists of several short news items. For each news there could be stored large archives or program material related to a particular story. Hence, through multimedia interaction with for, example, the remote control 900 the stored program material can be accessed. This would allow the user to review the material in whatever detail was desired.

Another example, is in an advertising feed if a particular item was advertised, there would be the ability to refer to more detailed information about the product via the Internet or other on-line services.

Yet another example of such a system is to have one service linked to another. An advertisement could be linked to a means for ordering the particular product being advertised including the placement of a phone call by the IMDs to the desired telephone number. In so doing, the linked system allows for additional services to be accessed.

The important requirements for this linked feature is that there is a knowledge of the contents of the system program requirements and there is a knowledge of where the user is in the program. For example, an IMD could be used for channel program identification in which the telephone call is linked to a particular channel that has been selected. Another example is link demographics for targeted interactive advertising. Hence, in an advertisement for a diaper, for example, there would be the facility to access advertisements for related items such as baby powder, baby oil or the like through the use of this linked

approach. Accordingly, this feature of the system can be utilized advantageously with the high speed Internet access described above to provide for enhanced interactivity. To more particularly describe these advantages refer now to the following examples.

5 Reservation System

A first example of this feature is a reservation system. Referring to Figure 13 which is a flow chart of such a system is selections can be reviewed via step 1302, then the customer can make a selection via step 1304 by reviewing the multimedia information on the television. If the selection is not available via step 1306 then the user can review
10 selections and make another choice. However, if the selection is available then the telephone system within the hotel is contacted by the MPS 102 via step 1308 so that the reservation can be made. Thereafter the reservation is made via step 1310.

An example of this could be the linking of an interactive voice response system to a multimedia system. In a preferred embodiment, a call can be linked to a particular website
15 in the Internet. For example, this system could be linked to a "900" number for the Wall Street Journal stock information. Thereafter, credit card verification can be entered by hand and/or by a credit card slot on the phone or the remote. More information could then be displayed, such as stock price graphs, on the TV synchronized with the latest news and price for the particular stock. Finally, system could allow for a voice annotated facsimile that
20 could be printed at the front desk of a hotel or the like. Alternatively the call and print synchronization could be accomplished by using a Web telephone connection through the Internet. This provides a connection from a website to a telemarketing group such as AT&T via the PBX.

25 Catalog Shopping

Another example of the use of this system is illustrated by catalog shopping. Referring now to Figure 14 in such a system there is updatable multimedia information that is viewed by a customer via step 1402 on the television monitor. Thereafter the customer can select from a number of shopping sources via step 1404. Whether the interactive
30 devices are in a central location or in a each room the customer can order by the device interacting with a catalog order desk located in the facility which then bills the customer via step 1406. The billing can occur directly through the account computer of the facility or on

the other hand can charged through a credit card transaction.

That transaction can be completed step via the credit card slot on the remote control 900, a credit card slot that may be located on the monitor or interactive device or telephone or finally the numbers on the credit card could be entered utilizing a remote control or the like. The MPS 102 can then generate a mail order facsimile directly to cataloger facsimile telephone line via step 1408. The MPS 102 then sends the order to the source via step 1410.

A customer receipt can then be printed at the front desk through a special printer and then the goods can then be delivered via steps 1412 and 1414. The goods could be delivered either to the hotel facilities, to the customers home or to her place of business. Finally, there could be variety of methods of delivery and there use would be within the spirit and scope of the present invention.

Accordingly, this system can be utilized effectively in a voice response system. Through the present invention a voice response can activate or operate in conjunction with a multimedia program to provide a fully interactive communication system. For example a facsimile message can be displayed on a television screen based on the voice response system.

Referring now to Figure 14a what is shown is an automated call processing system of Figure 14. In this embodiment the system places a call to the telephone number of the catalog source via step 1408-1, then the MPS 102 connects to the catalog source via step 1408-2 and send, an automated message such as "You have reached the cable network for ABC hotel, press 1 to confirm." After the connection is confirmed the MPS 102 it will then send order information to the catalog source via step 1410-1. The source will then acknowledge the order via step 1410-2. The source could for example confirm credit card information and the like during this step.

Video Reservation

Another example of the utility of the present invention is its use in a video reservation system within a hotel system or the like as shown in Figure 15. Through this system even those movies being viewed can be reviewed via step 1502. The customer can also determine when the video will be available via step 1504. The customer can the reserve the movie at a later time based upon the reviewed information via steps 1508 and 1510.

5 A variation on this type of system is illustrated in Figure 15a which is an allocated movie selection system. In this system movies could be viewed within a certain margin of time such as within 15 minutes after the hour step 1508-1. If the customer does want to see the movie, step 1510-1 then the movie is selected to be seen at the allocated time, if not the other choices can be viewed step 1508-1.

Ticket or Coupon Printing

10 Referring now to Figure 16 in a ticket or coupon printing system there is updatable multimedia information that is viewed by a customer via step 1602 on the television monitor. Thereafter the customer can select from a number of ticketing or couponing sources via step 1604 including on-line services. In a preferred embodiment, the customer could use an appropriate website for ticketing and various other information. This system can also be based upon demographic data to drive the coupon or ticket choices or attributes presented to the customer. Whether the interactive devices are in a central location or in a
15 each room the customer can order by the device interacting with an on-line service or the like through a high speed service center which then bills the customer via step 1606. The billing can occur directly through the account computer of the facility or on the other hand can charged through a credit card transaction.

20 In an Internet example, for ticketing, that transaction can be completed step via the credit card slot on the remote control 900, a credit card slot that may be located on the monitor or interactive device or telephone or finally the numbers on the credit card could be entered utilizing a remote control or the like. The MPS 102 can then generate a mail order facsimile directly to telephone line via step 1608. The MPS 102 then sends the order to the source via step 1610.

25 A customer receipt can then be printed at the front desk through a special printer. Then the tickets or coupons can then be delivered via steps 1612 and 1614. The tickets or coupons could be delivered either to the hotel facilities, to the customers home or to her place of business. Finally, there could be variety of methods of delivery and there use would be within the spirit and scope of the present invention.

30 This system would have particular utility in conjunction with multimedia yellow pages. Hence, the customer can review through advertising typical vendor information as found in the yellow pages except now this information is reviewed from a television.

Selections can be made using the remote control 900 to obtain certain information and thereby causing several related actions to occur. By placement of the telephone call a vendor could issue a ticket or coupon for a product or a service. An important feature for the printing of documents is the need for an inventory control system in which the customer can gain access to information that pertains to her transactions.

Map Printing

Referring now to Figure 17 in a map printing system there is updatable multimedia information that is viewed by a customer via step 1702 on the television monitor. Thereafter the customer can select from a number of mapping sources via step 1704. Whether the interactive devices are in a central location or in a each room the customer can order by the device interacting with a catalog order desk located in the facility which then bills the customer via step 1706. The billing can occur directly through the account computer of the facility or on the other hand can charged through a credit card transaction.

That transaction can be completed step via the credit card slot on the remote control 900, a credit card slot that may be located on the monitor or interactive device or finally the numbers on the credit card could be entered utilizing a remote control or the like. The MPS 102 can then generate a mail order facsimile directly to telephone line via step 1708. The MPS 102 then sends the order to the source via step 1710.

A customer receipt can then be printed at the front desk through a special printer and then the maps can then be delivered via steps 1712 and 1714. The maps could be delivered either to the hotel facilities, to the customers home or to her place of business. Finally, there could be variety of methods of delivery and there use would be within the spirit and scope of the present invention.

Inventory Control System

Referring now to Figures 18a and 18b what are shown is an electronic inventory control system 1800 and a physical inventory control system 1800'. Referring first to Figure 18A the electronic control system includes a personal computer 1802 with an associated display in this case a CRT display 1806. Also coupled to the personal computer is a keypad 1808 and a printer 1804. The printer in turn is coupled to an output device 1810. In such a system the keypad 1808 can be utilized by the customer in much the same way as an

automatic teller machine (ATM) in which the customer has a security code through the use of a room key to allow the customer to order tickets or make reservations via the personal computer 1802. The computer is linked to the MPS 102 to allow for secure access to the various sources of information. The display 1806 can be utilized to interactively operate with the personal computer to cause the printing out of the appropriate transactions via the printer 1804. The printer 1804, typically a laser printer or specialized ticket printing machine prints the information and provides that printed information or ticket to a secure output device 1810.

Figure 18B has similar elements to Figure 18a, however the physical system includes a tray for receiving the transactional information. Therefore each customer can have access to an individual tray of information by using their hotel key or the like. Through the inventory control systems shown in Figures 18a and 18b the customer has secure access to interactive multimedia transactions.

In yet a final example, the system can be configured for play along games. Accordingly, an interactive game could be provided which would allow for an individual to play a game such as chess, with another guest in the hotel or against a machine as in the case of a video game or the games could be played with sources outside the network through the on-line service.

It should be understood that the IMD 110 itself could be utilized as a call processing system. Finally, it should be understood that there could be multiple MPS 102 to provide for very large scale call processing through the MPC 109.

Although the present invention has been described in accordance with the embodiments shown in the figures, one of ordinary skill in the art recognizes there could be variations to the embodiments and those variations would be within the spirit and scope of the present invention. Accordingly, many modifications may be made by one of ordinary skills in the art without departing from the spirit and scope of present invention, the scope of which is defined solely by the appended claims.

CLAIMS

WHAT IS CLAIMED IS:

- 5 1. An interactive system for a closed cable network comprising :
 means for processing multimedia information received from an on-line
 service;
 means coupled to the multimedia processing means for controlling
 transmission of the multimedia information of the on-line service to the multimedia
10 processing means; and
 a plurality of multimedia devices coupled to the multimedia processing
 means to provide updatable multimedia information from the on-line service.
- 15 2. The system of claim 1 in which the plurality of multimedia devices includes
 a CD player.
3. The system of claim 1 in which the plurality of multimedia devices includes
 a personal computer.
- 20 4. The system of claim 1 in which the plurality of multimedia devices includes
 a video camera.
5. The system of claim 1 in which the plurality of multimedia devices includes
 a laser disk player.
- 25 6. The system of claim 1 in which the plurality of multimedia devices includes
 interactive multimedia decoder (IMD).
7. The system of claim 1 in which the plurality of multimedia devices includes
30 at least one interactive multimedia device and at least one video camera to provide a point to
 point video system.

8. The system of claim 1 in which the plurality of multimedia devices includes at least one interactive multimedia device (IMD) and at least one video camera to provide a point to point video system.

5 9. The system of claim 1 which further includes coupled to a multiplexer means coupled to an Interactive Multimedia Decoder (IMD), the multiplexer means for receiving inputs from the plurality of multimedia devices and for selecting from the plurality of multimedia devices to provide a multimedia output signal to the IMD.

10 10. The system of claim 1 which further includes a global multimedia multiplexer (GMM), the GMM further including means for receiving inputs from the plurality of multimedia devices, and for selecting from the plurality of multimedia devices to provide a composite multimedia output signal to a plurality of interactive multimedia decoders.

15 11. The system of claim 1 in which the plurality of multimedia devices includes at least one interactive multimedia device (IMD) and at least one video camera to provide a multipoint to point video system.

20 12. The system of claim 1 in which the system is utilized with a voice response system.

25 13. The system of claim 12 in which the voice response system provides a facsimile image on a display.

30 14. The system of claim 1 in which the controlling means comprises:
means for transmitting the multimedia information, the multimedia information including multiple layers,
means for separating the multiple layers of information into primary and secondary layers based upon a program model,
means for enhancing the primary layers through psychographic parameters in accordance with the program model,

means for providing the secondary layers through alternate psychographic parameters, and

means for combining the enhanced primary layers and the secondary layers to provide multimedia information that is a perceived improvement in quality.

5 15. The system of claim 1 in which the separating means further comprises means for interactively separating the layers based upon the program model into primary and secondary layers.

10 16. The system of claim 1 in which the primary layers are high bandwidth/high use information and secondary layers are low bandwidth/low use information.

 17. The system of claim 1 in which the enhancing means further comprises means for encoding the primary layers in accordance with a first compression algorithm.

15 18. The system of claim 1 in which the enhancing means further comprises means for encoding the primary layers in accordance with a first transmission algorithm.

20 19. The system of claim 1 in which the enhancing means further comprises means for encoding the secondary layers in accordance with a second transmission algorithm.

 20. The system of claim 1 in which the enhancing means further comprises:
 means for encoding the primary layers in accordance with a first
compression algorithm;
25 means for encoding the primary layers in accordance with a first
transmission algorithm;
 means for determining the perceived quality of the multimedia information;
if the perceived quality of the multimedia information is not acceptable;
 means for encoding the primary layers in accordance with another
30 compression algorithm;
 means for encoding the primary layers in accordance with another
transmission algorithm; and

means for repeating the encoding until the perceived quality of the multimedia information is acceptable.

21. The system of claim 20 in which the providing means further comprises means for encoding the secondary layers in accordance with a second algorithm.

22. The system of claim 21 which includes means for decoding the primary and secondary layers.

23. The system of claim 1 in which the psychographic parameters include color, temporal, audio, spatial, and material content.

24. The system of claim 1 in which the separating means is automatic.

25. The system of claim 24 in which the automatic separating means is accomplished via separate sources for the production of the primary and secondary layers.

26. The system of claim 24 in which the automatic separating means is accomplished via keying the primary and secondary layers to a the interactive multimedia information.

27. The system of claim 24 in which the automatic separating means is accomplished by spatially separating the primary and secondary layer.

28. The system of claim 24 in which the automatic separating means is accomplished by filtering the primary and secondary layers.

29. The system of claim 1 in which the controlling means comprises the steps of:
means for separating the multimedia information into separate layers with each layer having a particular psychographic parameter information composition for a particular program model,
means for applying a separate encoding for each of the separate layers of

multimedia information which maximizes the perceived quality of the multimedia information,

means for transmitting the separate encoded layers along different transmission mediums,

5 means for decoding the separate encoded layers, and

means for recombining the separate layers of multimedia information at a transmission end to provide an improved quality multimedia information.

10 30. The system of claim 29 in which the separating means comprises means for automatically separating the layers such that the psychographic parameters are interactively enhanced.

15 31. The system of claim 30 in which the automatic layers separation comprises providing the layers by separated production sources.

32. The system of claim 30 in which the automatic layers separation comprises keying the layers to the psychographic parameters.

20 33. The system of claim 30 in which the automatic layers separation comprises spatially separating the layers in accordance with the psychographic parameter.

34. The system of claim 30 in which the automatic layers separation comprises filtering the layers in accordance with the psychographic parameters.

25 35. The system of claim 29 in which the separating means comprises interactively separating the layers for highest program model quality and maximum interactivity.

30 36. The system of claim 34 in which the separating means further comprises means for interactively separating the layers into primary and secondary layers, the primary layers including the most important multimedia information to be transmitted.

37. The system of claim 36 in which the applying means further comprises means for encoding the primary layers in accordance with a first compression algorithm.

38. The system of claim 34 in which the psychographic parameter information includes spatial, temporal, audio and material content perception.

39. The system of claim 36 in which the applying means further comprises means for encoding the primary layers in accordance with a first transmission algorithm.

40. The system of claim 36 in which the applying means further comprises means for encoding the secondary layers in accordance with a second compression algorithm.

41. The system of claim 36 in which the applying means further comprises means for encoding the secondary layer in accordance with a second transmission algorithm.

42. A high speed access system of at least one on-line service in a closed cable system comprising:

an antenna for receiving satellite signals relating to the at least one on-line service; a communications controller coupled to the antenna means for converting the satellite signals to data signals; and

at least one computer workstation coupled to the communications controller for receiving the data signals from the communications controller to provide high speed access to the on-line service.

43. The high speed access system of claim 42 which includes a printer means coupled to the controller and the at least one workstation via a bus.

44. The high speed access system of claim 43 in which a plurality of computer workstations are coupled via a bus.

45. The high speed access system of claim 44 in which the outbound transmissions will be provided over conventional telephone lines while inbound communications will be provided over the antenna.

5 46. A system for interactively providing enhanced information related to a closed cable network, the system comprising:

means for linking an on-line service to a telecommunications service; and

means for synchronizing call and print information from the on-line service and telecommunications service.

10 47. The system of claim 46 including means for synchronizing the call and print information through a web site provided on the on-line service.

48. The system of claim 46 in which the linking can be provided through a hotel messaging system.

15 49. The system of claim 46 which further comprises:
means for separating the information into primary and secondary layer based on a program model;

means for storing the primary information locally; and

20 means for storing the secondary information remotely.

50. The system of claim 49 in which the program model could be a specified modeling language such as HTML.

25 51. The system of claim 49 in which the program model could be a specified modeling language such as VRML.

52. The system of claim 49 which includes means for controlling information via a keyboard via an infrared connection.

30 53. The system of claim 49 which includes means for controlling information via a telephone.

54. The system of claim 49 in which couponing or ticketing are linked via the Internet.
